Preface to the Second Edition Since the first edition of the book was published, a great deal of new material on principal component analysis (PCA) and related topics has been published, and the time is now ripe for a new edition. Although the size of the book has nearly doubled, there are only two additional chapters. All

Craig Syms, in Encyclopedia of Ecology (Second Edition), 2019. Introduction. Principal components analysis (PCA) is a distance-based ordination technique used primarily to display patterns in multivariate data. It aims to display the relative positions of data points in fewer dimensions while retaining as much information as possible, and explore relationships between dependent variables.

The second principal component is calculated in the same way, with the condition that it is uncorrelated with (i.e., perpendicular to) the first principal component and that it accounts for the next highest variance. This continues until a total of p principal components have been calculated, equal to the original number of variables.

The second principal component is perpendicular (orthogonal) to the first principal component and has the second largest variant. The underlying assumption is that the coordinates with the large variants most saliently demonstrate the contrast between sample points, while the coordinates with smaller variants may be a source of noise, which should be ignored or suppressed.

Usually, one summary index or principal component is insufficient to model the systematic variation of a data set. Thus, a second summary index - a second principal component (PC2) - is calculated. The second PC is also represented by a line in the K -dimensional variable space, which is orthogonal to the first PC.

Principal component analysis; PCA) Principal component analysis is a statistical technique that uses orthogonal transformations to convert a set of variables of possibly different units into a new set of variables of the same units. This new set of variables is the principal component analysis of the original set of variables. The principal component analysis of a set of variables is a set of orthogonal variables that are linear combinations of the original variables. The principal component analysis of a set of variables is a set of orthogonal variables that are linear combinations of the original variables. The principal component analysis of a set of variables is a set of orthogonal variables that are linear combinations of the original variables.
